BRUKHANKA

About Rukhanka

Rukhanka is an animation system for Entity Component System (ECS) for Unity Technology Stack. It depends on Unity Entities and Unity Entities Graphics packages.

Design and implementation of **Rukhanka** follows three principles:

- Trivial usage and interface
- Performance in all aspects
- Functionality and behavior are identical to Unity Mecanim Animation System

Simple Interface

Rukhanka has a very limited set of own user interfaces. It has no complex custom editor windows and configurable options. Everything related to animation functionality is set up using familiar Unity editors. At bake time, **Rukhanka** converts standard Unity Animators, Animation Clips, and Skinned Mesh Renderers into their internal structures and works with them in runtime.

Performance

Everything in **Rukhanka** is designed with performance in mind. All core systems are ISystem based and Burst compiled. Core animation calculation and state machine processing loops fully benefit from multi-core/multi-processor systems. Even debug and visualization functionality, despite that it can be completely compiled out, made Burst compatible as much as possible.

'Mecanim'-like behaviour

Rukhanka tries to mimic the behavior of the Unity Mecanim Animation System. It tries to do this during state machine processing as well as animation calculation and blending. Some parts of Mecanim have not been implemented yet/made similar by 100% in **Rukhanka**. Refer to *feature summary tables* for detailed information on compatibility and support features.

'Netcode for Entities' package Support

Rukhanka supports animation synchronization between server and clients in network games by working with 'Netcode for Entities' ECS library. Animation synchronization can be done by using predicted and interpolated ghosts. Client-only entities can coexist together with network-synchronized ones.

Upgrading Rukhanka

$[1.2.x \rightarrow 1.3.0]$

• The rig definition avatar mask asset is not needed anymore. Prepare your model to contain all necessary information by following the rig definition setup process. All previously created rig definition avatar mask assets can be safely deleted.

Getting Started

Prerequisites

To work with **Rukhanka Animation System** you need following:

- Unity 2022.3.0f1+
- Unity Entities package version 1.0.16+ (installed automatically as dependency)
- Unity Entities.Graphics package version 1.0.16+ (installed automatically as dependency)
- HDRP or URP as required by Entities.Graphics package
- [Optional] Netcode for Entities package for network animation synchronization support

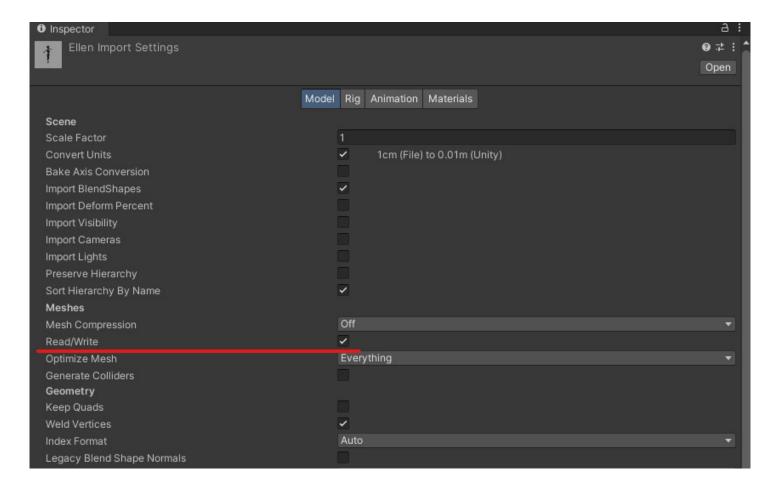

Animated Object Setup

To make animations work correctly there are some preparation setup steps are required.

Model Importer

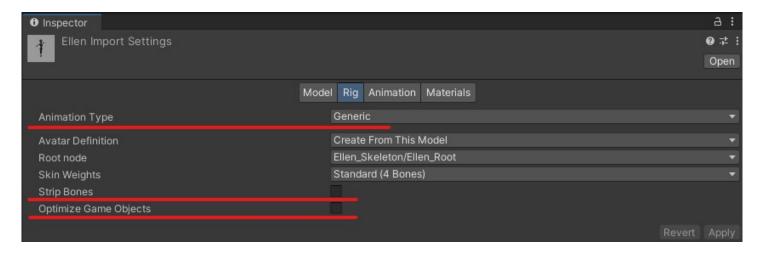

Use standard Unity model importer confuguration page to setup required model properties:

- 1. Model Importer Tab.
 - Enable Read/Write property for the mesh. This is requirement of Deformation Subsystem of Entities. Graphics package.

2. Rig Importer Tab.

- Set Animation Type to Generic or Humanoid.
- Uncheck Strip Bones checkbox. **Rukhanka** need full unmodified hierarchy for own avatar setup.
- Uncheck Optimize Game Objects checkbox. **Rukhanka** need all bone game objects in baking phase.

Rig Definition

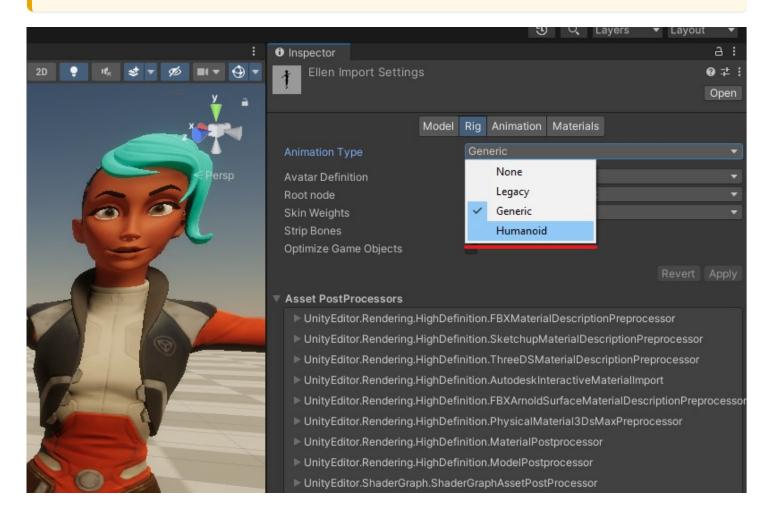

Rukhanka can get all required information about skeleton rig structure from Unity Avatar. There are several required simple steps to populate Unity Avatar with all necessary rig data:

1. In the importer window of your animated model switch Animation Type to the Humanoid and press Apply.

A IMPORTANT

You must do this for every model (even Generic). By switching to the Humanoid animation type Unity generates publicly available information about the skeleton rig structure that **Rukhanka** reads.

You will get an error during the baking process if avatar rig information is not available to **Rukhanka**.

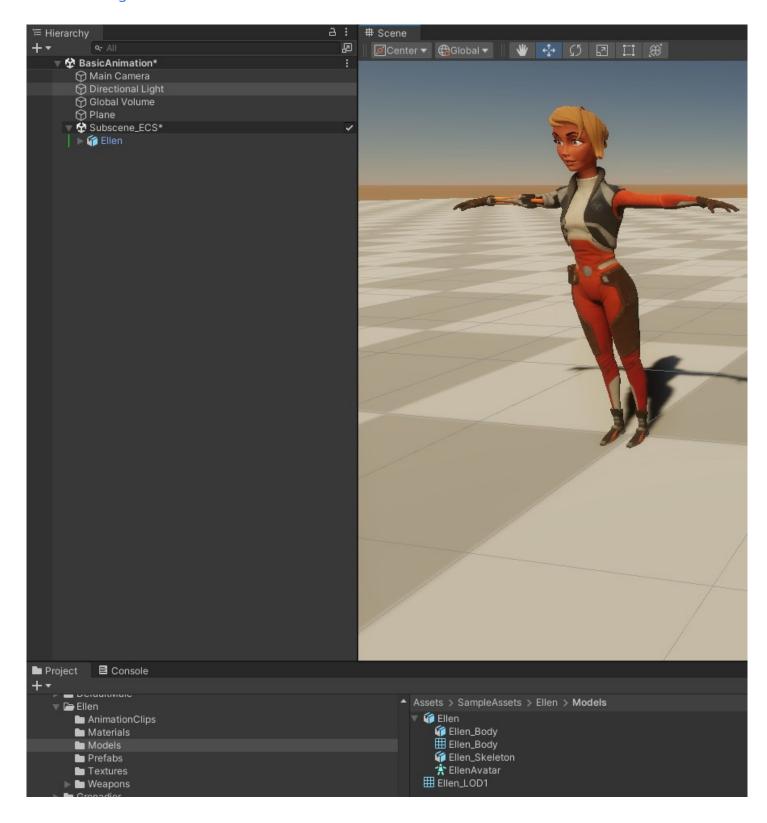

2. For Humanoid models configuration process is ended already. For Generic models you need to switch Animation Type of model back to Generic and press Apply.

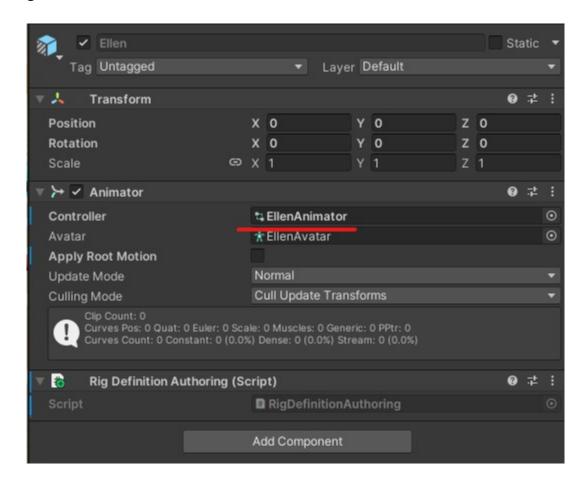

Authoring Object Setup

Final step is to create authoring GameObject inside Entities Subscene

1. Place your animated object inside Entities Subscene. For detailed description of this step refer Entites Package documentation.

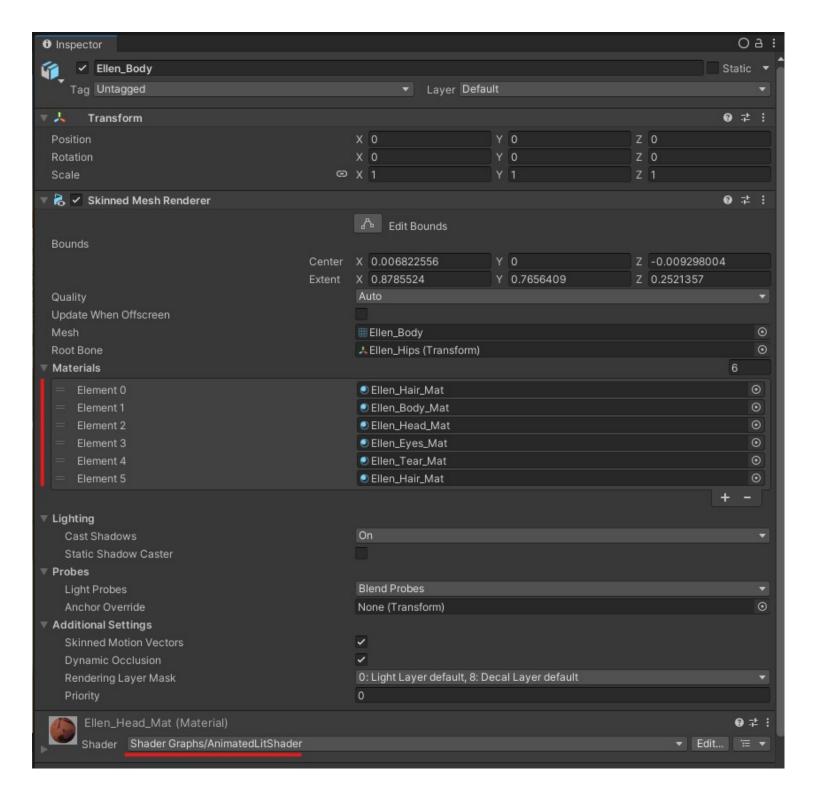

- 2. Add Rig Definition Authoring component to newly created object.
- 3. Create standard Animator Controller and fill it as you wish (one state with one animation will be a good start).

Shaders And Materials

Rukhanka does not render animated objects. It only prepares skin matrices for skinned meshes that are entirely managed by Entities.Graphics package. To be able to render deformed meshes correctly it is required to make Entities.Graphics compatible deformation-aware shader. Read carefully Mesh deformations section of Entities.Graphics package documentation. Make compatible shader using Unity Shader Graph or Amplify Shader Editor as described in the Shaders with Deformation page of this manual. Make and assign all required materials to your animated model.

End Of Setup Process

That's all needed to make **Rukhanka** be able to convert Animator Controller, all required Animations and own Rig Definition into internal structures. After that runtime systems will simulate state machine behaviour and play required animations.

IMPORTANT: There is not 100% Unity's Mecanim feature support. Please consult Feature Support Tables for complete information.

Here is video version of the entire *Getting Started* process

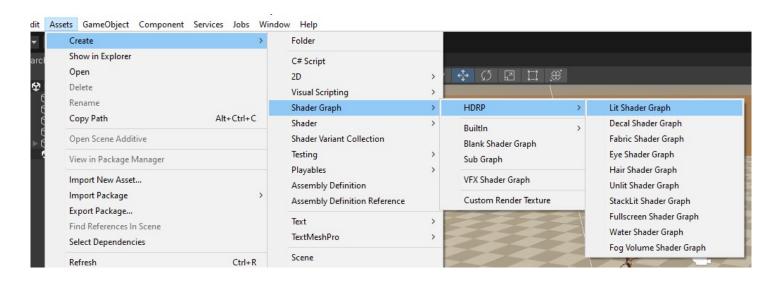

Shaders with Deformations

For the correct rendering of skinned meshes deformed by **Rukhanka**, an ECS deformation-aware shader should be created. To make this task Unity Shader Graph or Amplify Shader Editor tool can be used.

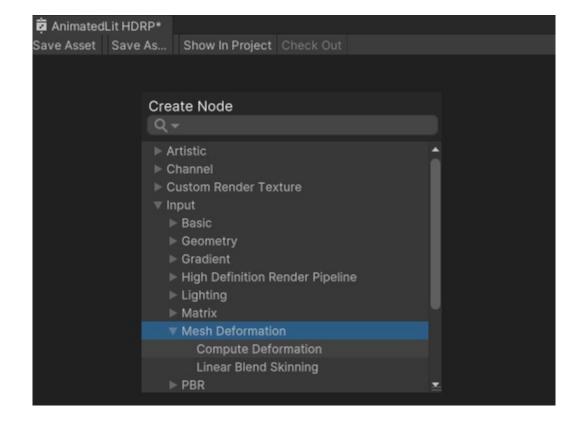

Unity Shader Graph

Creating deformation-compatible shaders using Unity Shader Graph is straightforward. The whole process is described in detail in mesh deformation section of official Entities Graphics documentation. The process consists of several simple steps:

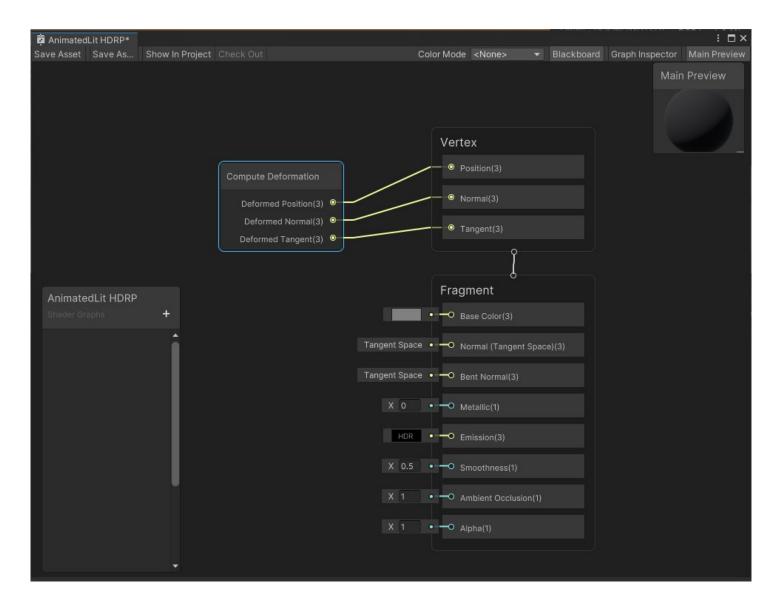

1. Create a shader graph (URP or HDRP depending on the render pipeline you are using) and open it for editing.

2. Add the Compute Deformation node to the Shader Graph.

3. Connect position, normal, and tangent output ports for the Compute Deformation node to the corresponding input ports of the master node.

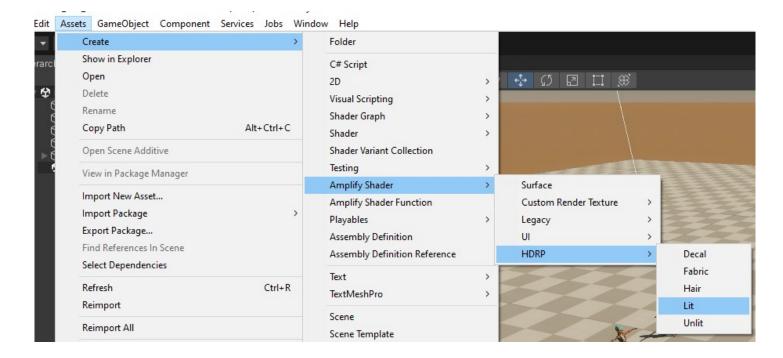

4. Save and assign this newly created shader to the materials of skinned mesh renderers.

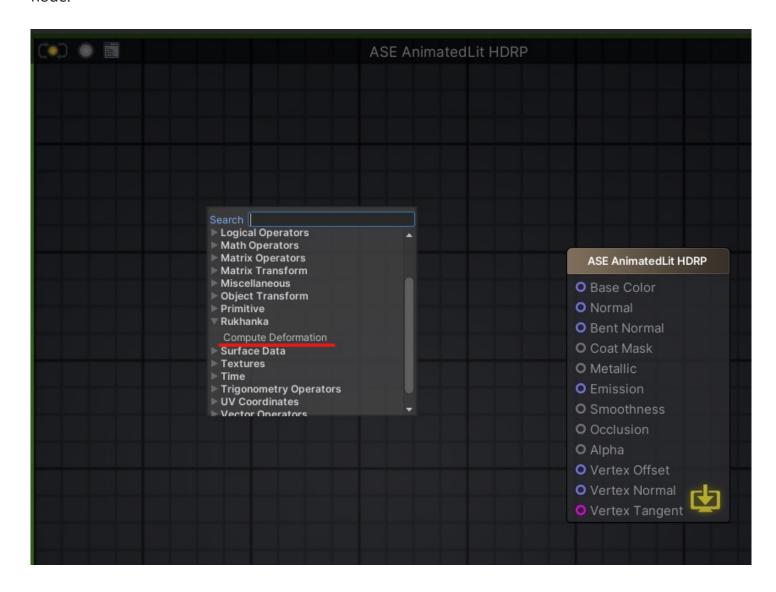

Amplify Shader Editor

Amplify Shader Editor tool has no Entities. Graphics compute deformation support out of the box, but **Rukhanka** adds necessary functionality to it. The process of creating deformation aware shader in Amplify Shader Editor is also simple:

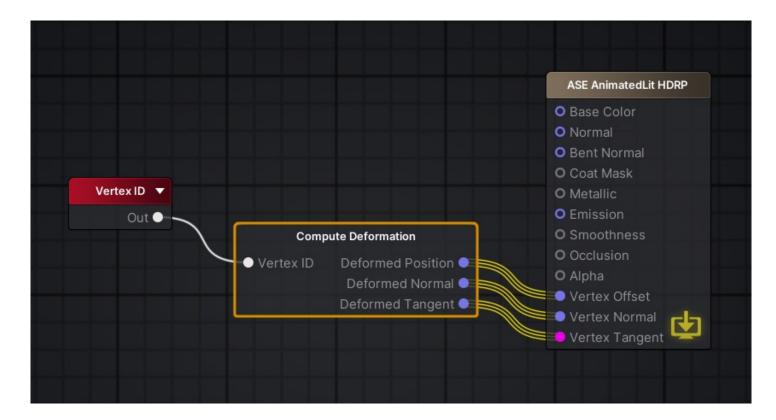

1. Create Amplify Shader and open it for editing.

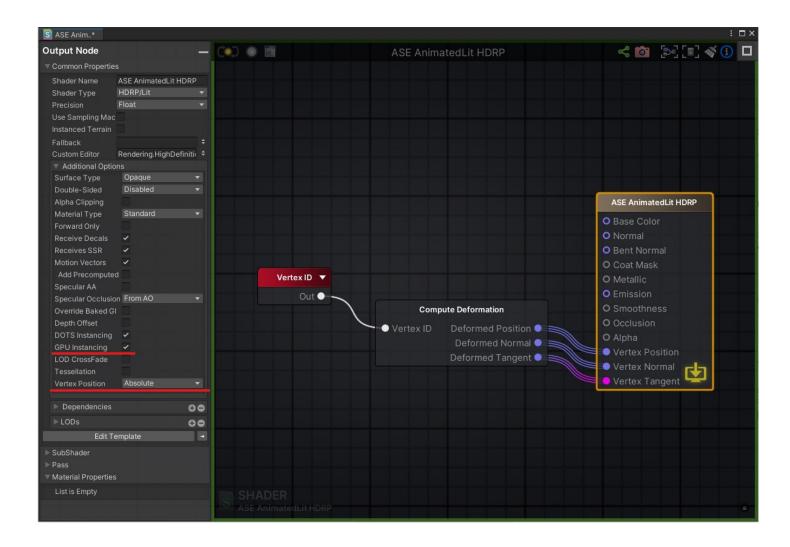

2. Open the Add Node dialog (Space or Right Click) and add the Rukhanka-> Compute Deformation node.

- 3. Add Vertex Data -> Vertex ID node.
- 4. Connect the Out port of the Vertex ID node with the Vertex ID port of the Compute Deformation node.
- 5. Connect the Deformed Position port of the Compute Deformation node with the Vertex Offset port of the shader master node.
- 6. Connect the Deformed Normal port of the Compute Deformation node with the Vertex Normal port of the shader master node.
- 7. Connect the Deformed Tangent port of the Compute Deformation node with the Vertex Tangent port of the shader master node.

8. Select the shader master node and enable the DOTS Instancing option, and set Vertex Position to Absolute.

Animator Parameters

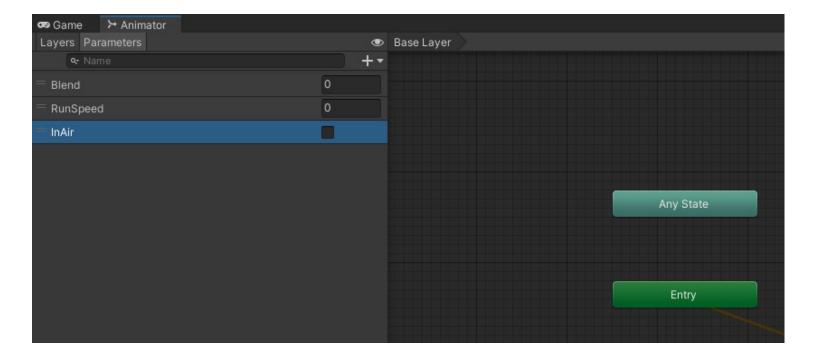

Direct Buffer Indexing

Rukhanka made DynamicBuffer for all animator parameters so the user can control its values from the code.

Basically, only DynamicBuffer with animator parameters is needed to access and manipulate parameter values. This is shown in the following code snippet:

```
[BurstCompile]
partial struct ProcessInputJob: IJobEntity
{
    void Execute(ref DynamicBuffer<AnimatorControllerParameterComponent> allParams)
    {
        var someParameter = allParams[0];
        // Increment parameter
        someParameter.FloatValue += 1.0f;
        // Put value back in the array
        allParams[0] = someParameter;
        ...
    }
}
```

This approach has only one advantage: access speed. Animator parameters are ordered in a way how they are defined in Unity's Animator from top to bottom. For example, in Animator parameters given in the next picture, there are three parameters: [0] - "Blend", [1] - "Run Speed", [2] - "InAir":

Perfect Hash Table

Accessing parameters by index has no name-value relationship. Any animator parameter reordering in Animator Controller will break the game logic code. So there is a better solution: accessing using a hash table. **Rukhanka** prepares Perfect Hash Table for a list of parameters during the baking stage. A perfect hash table is a hash table that has an unambiguous 'parameter name' -> 'array index' relationship. It is faster than ordinary hash tables and also has O(1) access complexity.

To simplify access to the parameters using a hash table, the helper class named [FastAnimatorParameter] is introduced. Follow these steps to access the animator parameter by name and in a very performant way:

• Define required FastAnimatorParameter's as, for example, system private fields:

```
public partial class PlayerControllerSystem: SystemBase
{
    FastAnimatorParameter blendParam = new FastAnimatorParameter("Blend");
    FastAnimatorParameter runSpeedParam = new FastAnimatorParameter("RunSpeed");
    FastAnimatorParameter inAirParam = new FastAnimatorParameter("InAir");
    ...
}
```

Pass prepared FastAnimatorParameters in the job:

```
protected override void OnUpdate()
{
    var processInputJob = new ProcessInputJob()
    {
        blendParam = this.blendParam,
        runSpeedParam = this.runSpeedParam,
        inAirParam = this.inAirParam
    };
    ...
}
```

• Query AnimatorControllerParameterIndexTableComponent component (it is the perfect hash table for a set of animator parameters) and use the FastAnimatorParameter methods to access parameter value:

```
[BurstCompile]
partial struct ProcessInputJob: IJobEntity
{
    public FastAnimatorParameter blendParam;
    public FastAnimatorParameter runSpeedParam;
    public FastAnimatorParameter inAirParam;
    void Execute(in AnimatorControllerParameterIndexTableComponent paramIndexTable, ref
DynamicBuffer<AnimatorControllerParameterComponent> allParams)
    {
        var t = paramIndexTable.seedTable;
        blendParam.GetRuntimeParameterData(t, allParams, out var blendParamvalue);
        blendParam.SetRuntimeParameterData(t, allParams, new ParameterValue() {
floatValue = blendParamValue + 1 } );
        inAirParam.SetRuntimeParameterData(t, allParams, new ParameterValue() {
boolValue = true } );
    }
}
```

Animator Parameters Aspect

To further simplify animator parameter access there is AnimatorParametersAspect is introduced. It has several methods for convenient parameter data access:

```
[BurstCompile]
partial struct ProcessInputJob: IJobEntity
    public InputStateData inputData;
    public FastAnimatorParameter floatParam;
    public FastAnimatorParameter intParam;
    public FastAnimatorParameter triggerParam;
    public FastAnimatorParameter boolParam;
    void Execute(ref AnimatorParametersAspect paramAspect)
    {
        paramAspect.SetParameterValue(floatParam, 2.2f);
        paramAspect.SetParameterValue(intParam, 42);
        paramAspect.SetParameterValue(boolParam, true);
        paramAspect.SetTrigger(triggerParam);
        var floatValue = paramAspect.GetFloatParameter(floatParam);
       var boolValue = paramAspect.GetBoolParameter(boolParam);
    }
}
```

Some functions of AnimatorParametersAspect accept FixedString with parameter names. Those variants are slower than with FastAnimatorParameter and created mostly for easiness of quick prototyping and should not be used in final high performance code.

Entity Components

Rukhanka conceptually consists of two main modules:

- Animator controller
- Animation processor

Each module has its own baker system that prepares data for it by converting appropriate authoring components (Unity Animator, Unity Skinned Mesh Renderer, and Unity Animations)

Animator Controller System

The main function of the controller is advancing the animation state machine with time and preparing required animations for the current state and transitions. The animator controller system processes entities with the AnimatorControllerLayerComponent component array. Each element in this array represents separate animation layer as specified in Unity Animator.

```
public struct AnimatorControllerLayerComponent: IBufferElementData, IEnableableComponent
{
    ...
}
```

AnimatorControllerLayerComponent is inherit IEnableableComponent so can be enabled and disabled. If disabled, the state machine of this owning entity will not be processed, and the model stops its animations (pose will be paused). After enabling the state machine will continue from the moment of pause.

During state machine processing, all prepared animations will be arranged in form of an array of AnimationToProcessComponent components.

```
public struct AnimationToProcessComponent: IBufferElementData
{
    ...
}
```

Animation Process System

This system reads the AnimationToProcessComponent array, samples animations at specified times and blends results according to required blend rules. The animated entity is defined as RigDefinitionComponent:

```
public struct RigDefinitionComponent: IComponentData, IEnableableComponent
{
    ...
}
```

This component is also inherited from <code>IEnableableComponent</code> and can be enabled or disabled accordingly. In disabled state, all animations for an entity are not processed, but the corresponding state machine will continue its work and still provides the rig with updated animation data. After enabling <code>RigDefinitionComponent</code>, animations will jump to the actual state machine animation state.

Animator State Query

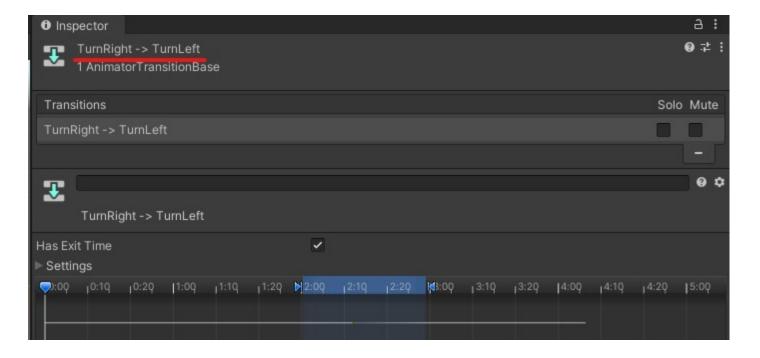

It is possible to query the runtime animator's internal state using the AnimatorStateQueryAspect aspect. State and transition data returned by this aspect contain a hash of state/transition respectively and normalized time (how much time controller is in this state/transition). To find out the required state, the hash value of it must be calculated upfront. This should be done by constructing FixedStringName with a state name. For example, a state with the name "Idle Random" can be used as follows:

```
var stateNameFull = new FixedStringName("Idle Random");
```

Hash code can be obtained from this string by calling CalculateHash32() member function:

```
var stateHash = stateNameFull.CalculateHash32();
```

For transitions, the process is the same:

```
var transitionName = new FixedStringName("Turn Right -> Turn Left");
var transitionHash = transitionName.CalculateHash32();
```

Here is a usage example of AnimatorStateQueryAspect:

```
public partial struct MySystem : ISystem
{
    uint myStateHash, myTransitionHash;
    public void OnStart(ref SystemState state)
        myStateHash = new FixedStringName("State Name").CalculateHash32();
        myTransitionHash = new FixedStringName("State Name -> State Other
Name").CalculateHash32();
    }
    public void OnUpdate(ref SystemState state)
        foreach (var animatorState in SystemAPI.Query<AnimatorStateQueryAspect>())
        {
            // Specify required layer index of animator.
            var layerIndex = 0;
            // Get animator current state
            var runtimeState = animatorState.GetLayerCurrentStateInfo(layerIndex);
            // Use received RuntimeStateInfo structure to access to the current state
hash, and normalized state time
            if (runtimeState.hash == myStateHash)
            {
                // Do something...
            }
            // Get current transition
            var transitionState = animatorState.GetLayerCurrentTransitionInfo(layerIndex);
            if (myTransitionHash === transitionState.hash)
            {
                // Do something...
        }
    }
}
```

If the RUKHANKA_DEBUG_INFO script symbol is defined in the project, RuntimeTransitionInfo and RuntimeStateInfo structures will contain a name field with a transition/state symbolic name in it. There is an example named Animator State Query in **Rukhanka** samples. It shows described above features.

Non-skinned Mesh Animation

Rukhanka can animate arbitrary Entity hierarchy. The process is essentially the same as for ordinary skinned meshes:

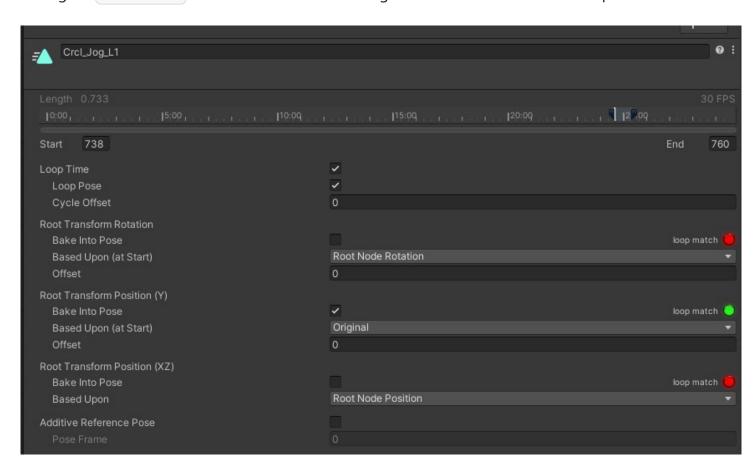

- Create an Animator and define animations in it.
- Place an object on subscene and add the Rig Definition Authoring Unity component to it.
- Add Unity Animator component, and assign the Animator state machine to it.
- **Rukhanka** will automatically create a rig for a given model starting from the node with Rig Definition Authoring assigned.

Root Motion

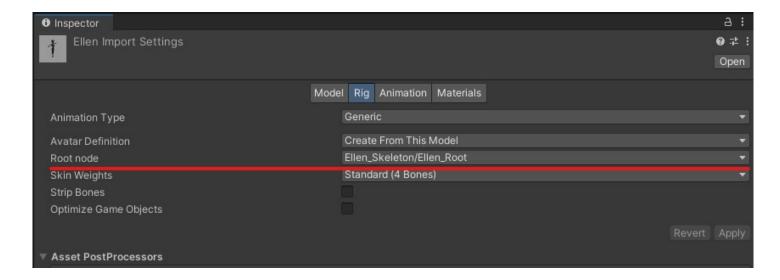

Rukhanka has full root motion support for humanoid and generic avatars and animations.

Follow these steps to enable root motion for your model:

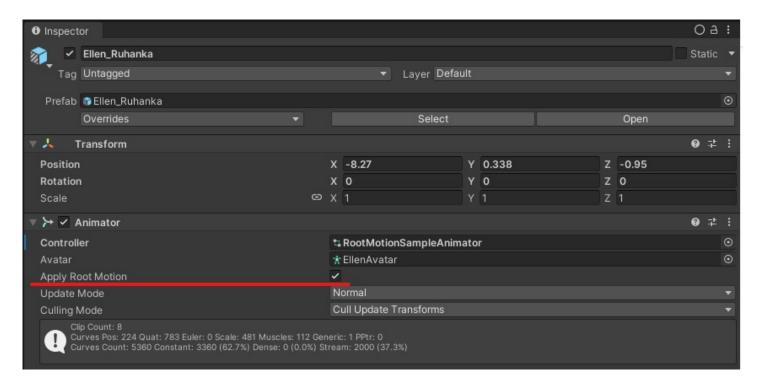

• Configure Root motion as usual from motion configuration section of animator importer window:

• Configure Root node field in model importer window to the bone that will be used to drive object movement.

• Enable the Apply Root Motion checkbox in the Unity Animator component:

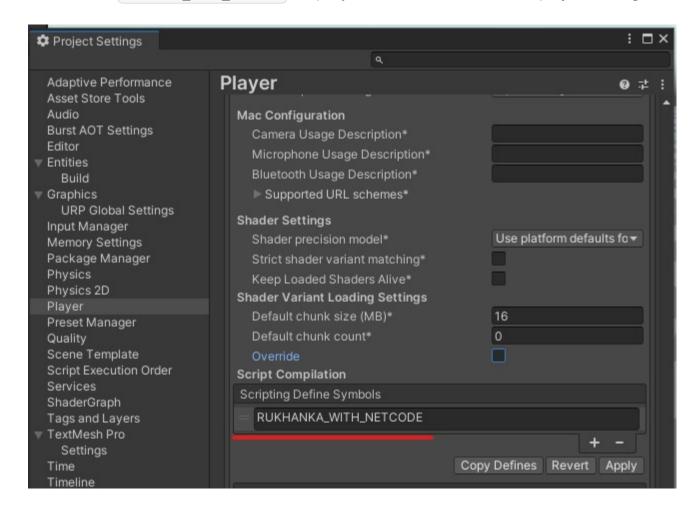

User Curves

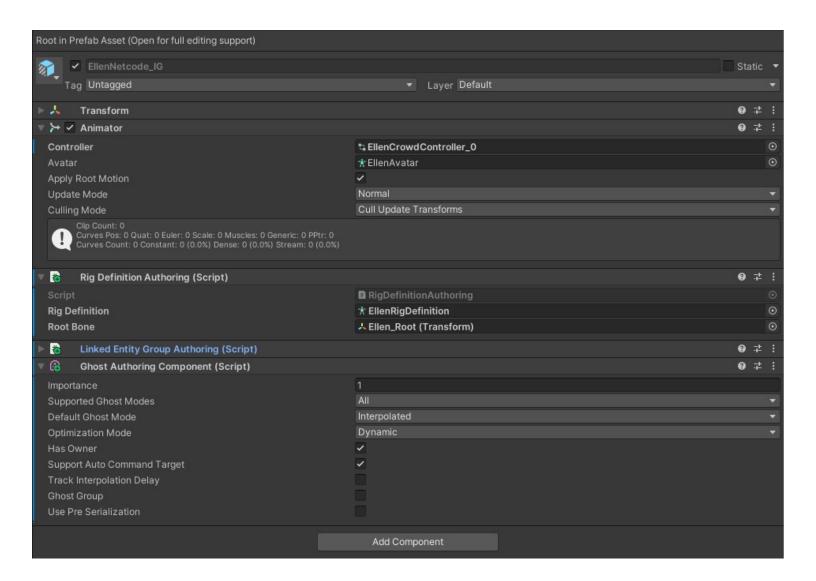

Rukhanka has user curves support. These curves can drive animator parameters exactly as Unity Mekanim does. Specify the user animation curve exactly as described in documentation. Make sure its name is the same as one of your animator controller parameters. **Rukhanka** will process these curves and writes the current value to the corresponding parameter component data.

Working with Netcode

Rukhanka has full Unity Netcode for Entities package support. Network animation synchronization is available for predicted and interpolated ghosts. By default, **Rukhanka** is a client-only library. This means that it exists only in the client entity world. No data replication from server to clients is performed by the Netcode package. For configuring **Rukhanka** to be able to synchronize the state of animated entities over the network RUKHANKA WITH NETCODE script symbol should be defined in project settings.

After that setup replicated prefab as described in the Netcode package documentation.

Both types of ghost modes are supported. For predicted ghosts, there is a prediction version of AnimatorControllerSystem running in Predicted Simulation System Group. For interpolated ghosts animation data received from a server is used as is in animation calculation. Client-only animated entities (entities that do not require synchronization) will work as usual.

There is a special demo made for **Rukhanka** Netcode features showcase.

Working with Physics

Attached Physics Bodies

Physics bodies get unparented by Unity. Physics to work properly. **Rukhanka** will correctly animate an unparented bone entity.

A IMPORTANT

It is not immediately obvious, that a rigid body should be constructed in bone entity and not as child object of bone entity. In the latter case child entity will be unparented and lose connection with the animated bone. Please refer to the Simple Physics sample scene for setup example.

Ragdoll

Rig bone without animation will be driven by its LocalTransform component. This allows us to make a setup where bodies will drive animated bone positions and orientations. The Ragdoll sample scene will show this behavior.

Samples

Installation

Navigate to the Resources/Rukhanka Animation System/Samples directory. Import the RukhankaSamples_HDRP.unitypackage or RukhankaSamples_URP.unitypackage (depending of your rendering pipeline) package into your project. All sample scenes will be located at Assets\RukhankaAnimationSystem\Samples.

Basic Animation

This sample is a result of the Getting Started page of this documentation. The sample scene contains several models that play one animation each.

Bone Attachment

Entities (animated and non-animated) are handled by **Rukhanka** automatically. No extra special steps are needed. Just place your object as a child of the required bone <code>GameObject</code>. Entity hierarchy will stay intact, but **Rukhanka** will move corresponding <code>Entities</code> according to animations. This sample shows this functionality.

Animator Parameters

This sample has an animated model with a simple Animator created for it. Parameters that control Animator behavior are controlled by a simple system through UI. Controlling animator parameters from code described in Animator Parameters section of this documentation

BlendTree Showcase

Rukhanka supports all types of blend trees that Unity Mecanim does. This sample shows Direct, 1D, 2D Simple Directional, 2D Freeform Directional, 2D Freeform Cartesian blend tree types. Blend tree

blend values can be controlled from in-game UI.

Avatar Mask

Avatar Masks is supported for generic and humanoid animations. The use of this feature is no different than in Unity. Specify Avatar Mask and use it in Unity Animator to mask animation for bones. **Rukhanka** converts it into internal representation during the baking phase. This sample shows this functionality.

Multiple Blend Layers

Rukhanka has multiple animation layers support. Additive and Override layers with corresponding weights are correctly handled by **Rukhanka** runtime. In this sample, Animator simulates two layers represented by simple state machines.

User Curves

Custom animation curves are handled the exactly same way as they do in Unity Mecanim. If the animation state machine has a parameter with a name equal to the animation curve name then the value of the calculated curve at a given animation time will be copied into the parameter value. In this sample, there is an animation that has a curve whose name is the same as the animation speed parameter of the Animator state machine. This way animation controls its own speed. User curves are described in more detail in the User Curves section of the documentation.

Root motion

Rukhanka has limited [Root Motion] support. This sample demonstrates its use case. Root Motion features are described in detail in the corresponding section of documentation.

Animator Override Controller

Unity Animator has a feature called Animtor Override Controller. This feature enables to use of a different set of animations for a given preconfigured Animator. This feature is also supported by **Rukhanka**. This

sample has an Animator Controller and corresponding Animator Override Controller which overrides several animations.

Non-Skinned Mesh Animation

Rukhanka can animate arbitrary Entity hierarchy with user-defined animation. This sample shows this use case. Refer to the Non-skinned Meshes page for a detailed description of this feature.

Crowd

This sample shows **Rukhanka** ability to animate a big number of different animated models. A simple prefab spawner system is used to spawn big counts of prebaked animated prefabs.

Stress Test

This sample is basically the same as the Crowd sample but with all skinned mesh models replaced by plain cubes. This step removes the big graphics pipeline pressure of the Crowd scene and keeps only raw **Rukhanka** animation system performance. This sample scene can be used for checking animation performance limits for tested systems/hardware.

Netcode Demo

Netcode demo is made for showing **Rukhanka** ability to work with the Unity Netcode for Entities package to achieve client-server animation synchronization in a network game. The RUKHANKA_WITH_NETCODE script symbol should be defined for proper demo functionality.

Three types of objects that can be instantiated on the scene:

• Local client only. Those prefabs exist only in the client world and therefore not synchronized between client and server. To spawn such objects use the Spawn Local button. Client-only prefabs have a default coloring scheme to distinguish them:

Interpolated ghosts. They are colored with red-tinted materials:

• Predicted ghosts. They are colored with green-tinted materials:

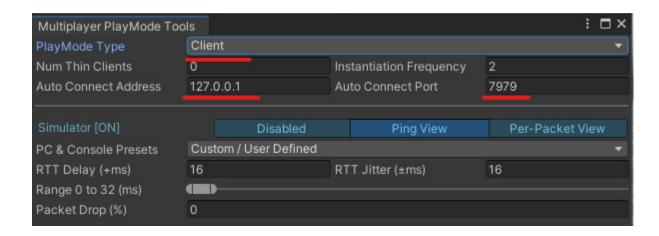

Both network synchronized prefab types can be created by pressing the Spawn Networked button:

After this demo scene has been started both client and server worlds are created and the client automatically connects to the server. To observe interpolation and prediction behavior it is advised to use PlayMode Tools of the Netcode package. By simulating various packet loss and RTT conditions, differences between ghost modes can be observed in this sample.

To even better experience you can make a build with this scene, run it and then connect with another client instance directly from the editor by modifying the play mode type in PlayMode Tools. Use IP address 127.0.0.1 (localhost) and port 7979:

Using this test environment you can spawn networked prefabs from both of the clients and watch how they are replicated by the server.

Animator State Query

This sample shows the usage of the runtime animator query aspect. Every frame animator queried for its runtime state and transition and received information shown in scene UI.

Humanoid Animations

This sample shows humanoid avatar and animations usage. It has several controls that can be used to alter animation state machines and watch animation changes for sample models.

Simple Physics

Staring from v1.4.0 **Rukhanka** has an ability to work with unparented (flat) bone hierarchies. This allows to properly attach the Unity.Physics bodies to the **Rukhanka** skeleton bones. This sample shows described functionality.

Ragdoll

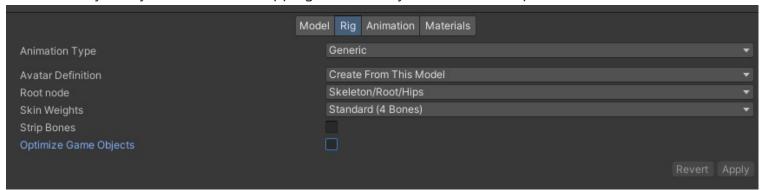

Bone entities can drive animated bone placement in animation rig. Ragdoll sample have very simple preconfigured physics ragdoll. When animations are not played for animated entity, physics simulation will drive animated bone positions.

Optimizing Rukhanka

Optimizing Bone Entities Count

By default, every animated skeleton bone has a corresponding entity in the ECS world. These entity positions get updated with computed animations by **Rukhanka**, and the hierarchy is processed by entity transformation systems. With a high bone count, updating these entities will take a significant amount of processing time. Often these bone entities are not needed, at least not all of them. It is advisable to keep only bones that are required for gameplay (bones with attachments, for example). **Rukhanka** provides functionality to strip unneeded bone entities.

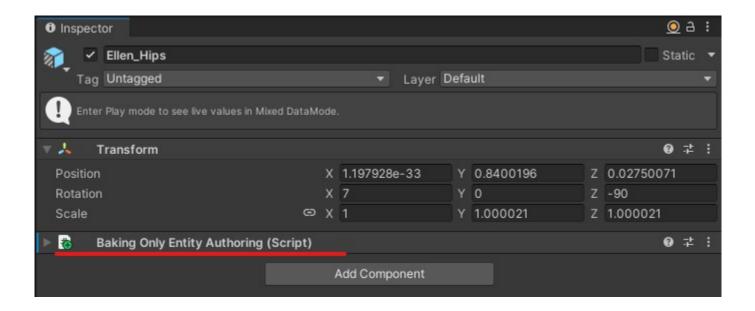

Unfortunately, Unity's builtin bone stripping functionality of the model importer window cannot be used:

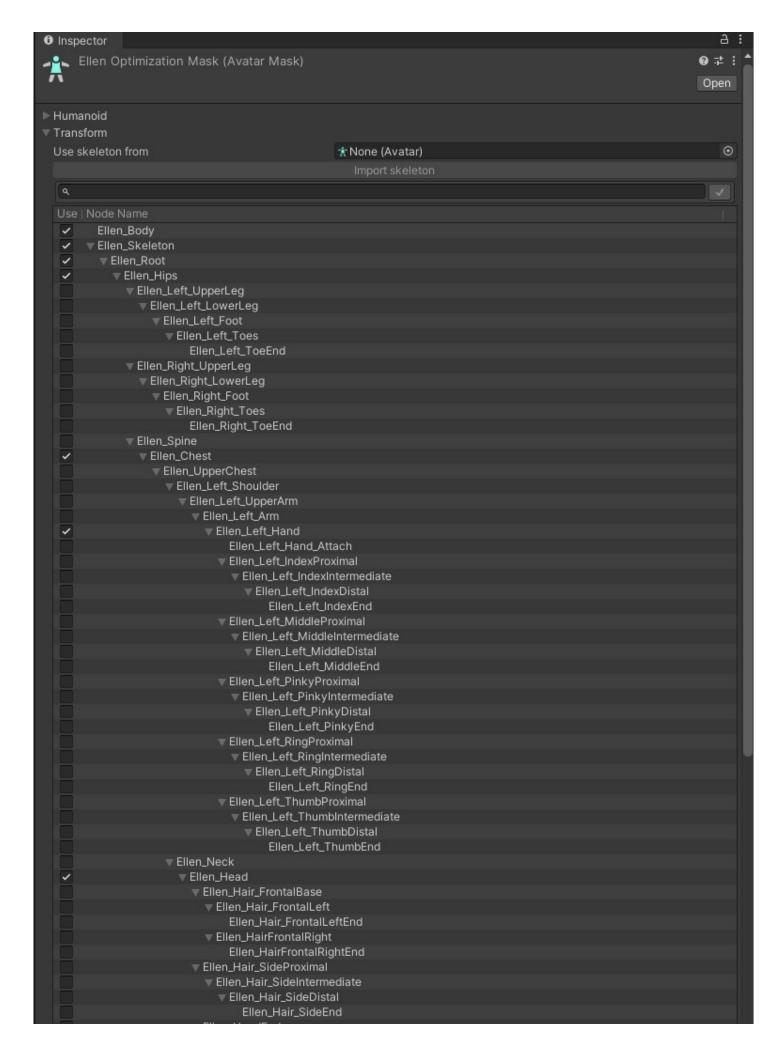

Rukhanka reads full hierarchy information from Unity avatar during the baking phase, so both Strip Bones and Optimize Game Objects checkboxes should be **unchecked**.

To remove unneeded entities from the ECS world there are two options available:

• Use the BakingOnlyEntityAuthoring component provided by the Entities package. By adding this component, the entity corresponding to this GameObject and all of its children will be stripped from the ECS world. Unfortunately, there is no option to configure its behavior for keeping some of its children (often attachments are bound to the bone deeper in the hierarchy). This approach is very good for situations when the model does not have attachments at all. Adding the BakingOnlyEntityAuthoring component to the rig root bone will strip the entire bone entities hierarchy.

• If more precise stripping granularity is needed, then a special bone mask can be used. Optimization mask is just the default Unity AvatarMask object. Fill it with the specifying avatar in the Use skeleton from field and press the Import skeleton button. Enabled bones in it will stay as entities and disabled ones will be stripped:

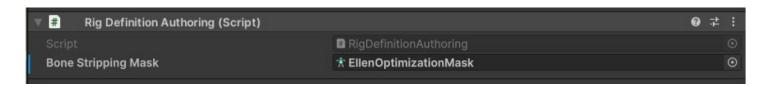

Ellen_HeadEnd

▼ Ellen_Jaw

Ellen_JawEnd

Ellen_Left_LowerMouth

• Then set the configured avatar mask in RigDefinitionAuthoring:

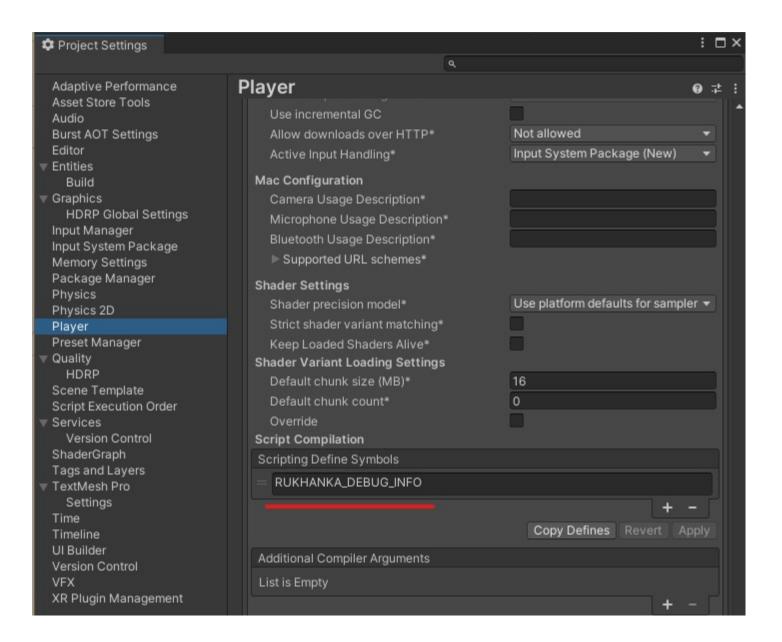

By using a bone stripping mask whole entity bone hierarchy will be flattened (i.e. Parent component will be removed from bone entities). Unparented bones must have a valid animation track (just one identity keyframe will suffice) associated with it to be animated correctly. Otherwise, the bone will be driven by LocalTransform component values, which is a world pose if the parent is not present.

Debug and Validation

Extended Validation Layer

Despite that the animation system heavily depends on name relations between components (bone names, animation parameter names, state machine state names, etc), string values are used only in bake time. Bake systems convert all string values into Hash128 representations and work with them in runtime. No string data is available during state machines and animation processing. This approach is very performant but debugging and validation in case of issues become very complicated.

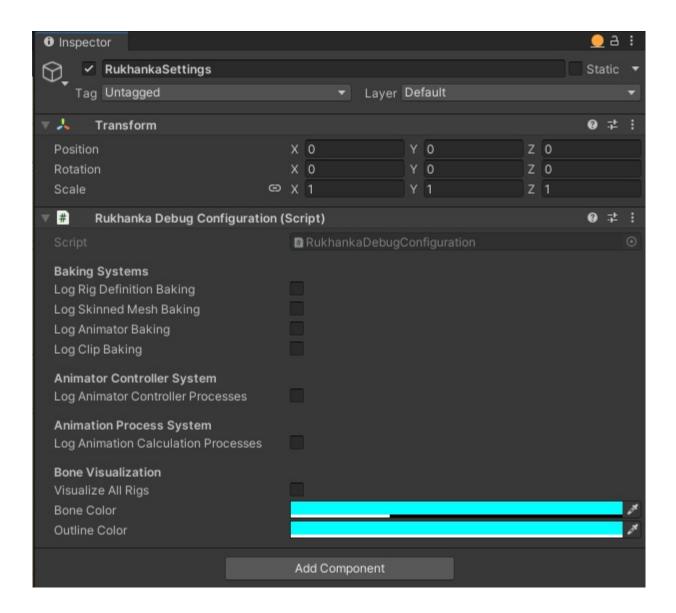

To make the easier process of watching for state and parameter changing, debugging, and detailed logging of baking processes, **Rukhanka** introduces a special extended validation mode. This mode can be enabled by adding the RUKHANKA_DEBUG_INFO script definition symbol into project preferences:

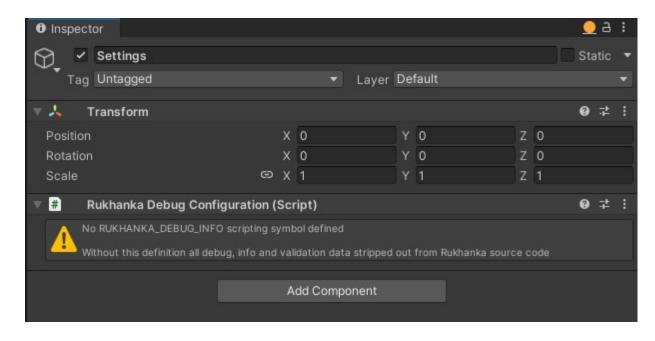

Adding this symbol, **Rukhanka** will add to all internal structures its corresponding string fields (FixedString or BlobString for Burst compatibility where appropriate). Watching these members in the debugger and logging makes it much easier to investigate and fix problems in animations

Logging capabilities

By defining RUKHANKA_DEBUG_INFO extended logging and visualization capabilities have also become available. To configure them add the Rukhanka Debug Configuration authoring component to any GameObject inside Entities Subscene.

If RUKHANKA_DEBUG_INFO is not defined this configuration script will show a warning message and no configuration options will be available:

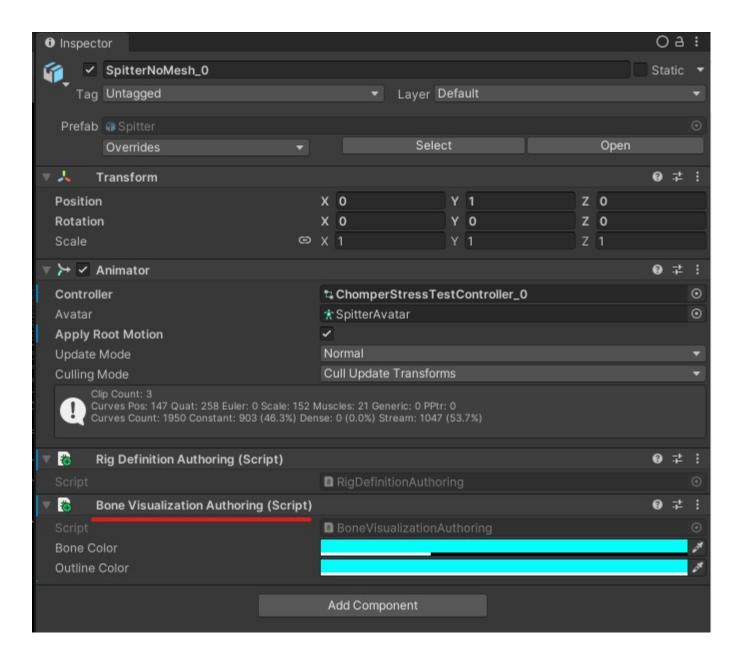

- Baking Systems logging will log a total of Authoring Components baked as well as additional warnings and messages during the baking process.
- Animator Controller System logging will enable the log of animator controller internal state changes and additional details.
- _Animation Process System__ logging will enable the log of animation core internal details during runtime.
- Bone Visualization enables internal bone renderer for all Rukhanka Rigs.

Bone Visualization

There are two options to enable Bone Visualization capability for Rukhanka Rig:

- 1. Enable bone visualization for all meshes in the scene. This is done by the checkbox described in the previous section on this page.
- 2. Add the Bone Visualization Authoring component to the required animated object. Note that this way bone visualization will work even without RUHANKA_DEBUG_INFO defined.

Changelog

[1.4.0]

Fixed

- Several memory leaks during baking and runtime.
- Incorrect additive animation calculation for humanoid animations.

Added

- Two new sample scenes: Ragdoll and Simple Physics.
- Animation keyframe binary search was implemented.
- Rukhanka can now work with unparented bone entities. This allows to properly handle physics body bone attachments.
- Unneeded bone entity stripping functionality. Refer to documentation for the detailed description.
- Internal bone animation data is now exposed as a RuntimeAnimationData singleton.
- Full root motion support for Humanoid and Generic rigs. All root motion animation configuration parameters are supported.
- **Rukhanka** now requires UNITY_BURST_EXPERIMENTAL_ATOMIC_INTRINSICS script compilation symbol. It will be added to project scripting define symbols automatically if not present.

Changed

- Updated Entities dependency to version 1.0.16.
- Removed synchronization point related to AnimationToProcess buffer filling.
- Removed synchronization point related to root motion delta states processing.
- The animation process system is split into two distinct parts: animation calculation and animation application. This allows to injection of animation results post-processing and modifications (for example IK) functionality.
- Runtime created bone-name-to-index hash map was removed. It has been replaced with a blob perfect hash map created during baking time.

- Samples were moved to the samples tab of package properties. There are shared HDRP/URP sample scenes now. Materials and scene properties will adapt to the current renderer pipeline automatically.
- Animation controller layer weight is a runtime property of AnimatorControllerLayerComponent now.

[1.3.1]

Fixed

Fixed compilation errors during standalone builds creation.

[1.3.0]

Added

- Humanoid-type support for models and animations.
- Humanoid avatar mask support.
- Humanoid avatars and animations sample scene.

Changed

• The rig definition authoring script now contains zero configuration fields. The avatar mask used for rig definition is not needed anymore. All required information **Rukhanka** reads from Unity Avatar. This is a breaking change. Please carefully read the upgrade process.

Fixed

• AnimatorControllerParameterComponent buffer did not replicate with NetCode.

[1.2.1]

Fixed

• Fixed compilation errors during standalone builds creation.

[1.2.0]

Added

- Compute deformation node for Amplify Shader Editor. Now it is possible to make Entities. Graphics deformation-compatible shaders with this tool.
- Trigger set API for AnimatorParametersAspect.
- The animator parameter access performance tests.
- Own entity command buffer system for optimizing ECB usage after AnimationControllerSystem.
- AnimatorStateQuery aspect for access to runtime animator data.

Changed

• Animator parameter internal hash code representation was moved from [Hash128] to uint. This leads to a smaller AnimatorControllerParameterComponent size and better chunk utilization.

Fixed

- The state machine states without an assigned motion field had incorrect weight calculations.
- Exit and enter transition events that happened in the same frame lead to one incorrectly processed frame. This was clearly observable with transitions from/to "no-motion" states.
- Trigger parameters were reset even if the transition cumulative condition (all conditions must be true) is not met.
- Entering through the sub-state machine's Enter state was handled incorrectly.
- Exiting from nested sub-state machines using the Exit state was handled incorrectly.
- Multiple transitions from the Enter state machine state were handled incorrectly.

[1.1.0]

Added

- Unity Netcode for Entities package support. Animations and controllers can be synchronized using interpolated and predicted modes.
- New Netcode Demo sample with **Rukhanka** and Netcode for Entities collaboration showcase.

• Animator parameter aspect to simplify animator controller parameter data manipulation.

Changed

Minimum Entities and Entities. Graphics packages version is 1.0.10.

Fixed

- State machine transitions with exit time 0 were handled incorrectly.
- Transitions with exit time 1 are looped contrary to Unity documentation. **Rukhanka** behavior changed to match Mecanim in this aspect.
- Various deprecated API usage warnings.

[1.0.3]

Added

- Adding authoring Unity. Animator and all used Unity. Animation in the baker dependency list.
- Extended animator controller logging with RUKHANKA_DEBUG_INFO which displays all states parameters and transitions of baked state machines.

Fixed

- Incorrect handling of very small transition exit time during state loops.
- Preventing NANs (division by zero) when transition duration is zero.
- Memory allocation error in PerfectHash tests.
- Controller parameters order in authoring animator does not coincide with generated AnimatorControllerParameter buffer.
- Empty animations to process buffer were handled incorrectly.
- Exit states of state machines are now handled properly.
- Animator state Cycle Offset treated as animation normalized time offset as in Unity. Animator.

[1.0.2]

Fixed

• Entities 1.0.0-pre.65 and Entities. Graphics 1.0.0-pre.65 support.

[1.0.1]

Added

- IEnableableComponent interface for AnimatorControllerLayerComponent and RigDefinitionComponent.
- Decsription of main **Rukhanka** entity components.

Changed

- Crowd and Stress Test samples now have control for skeleton visualization enabling (with RUKHANKA_DEBUG_INFO defined).
- Crowd and Stress Test samples now show total number of animated bones in scene.

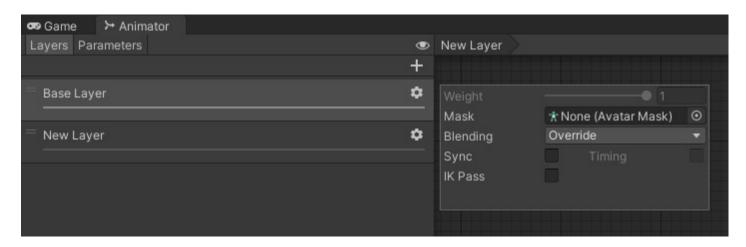

Fixed

• Incorrect handling handling of uniform scale in animations.

[1.0.0] - Initial release

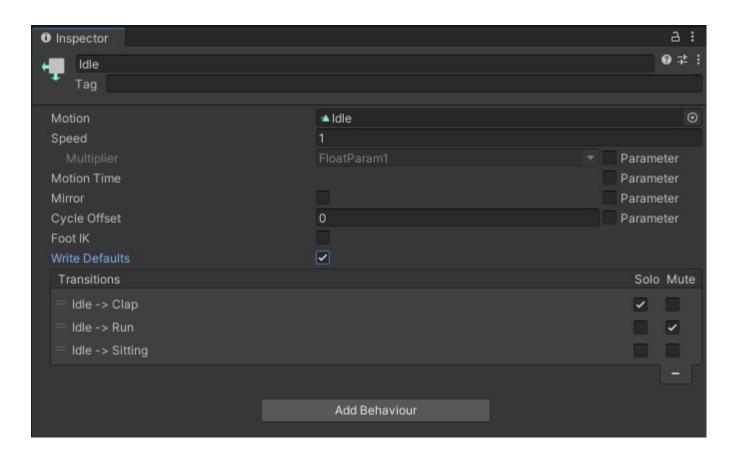

Feature Support Tables

Animator Controller Layer

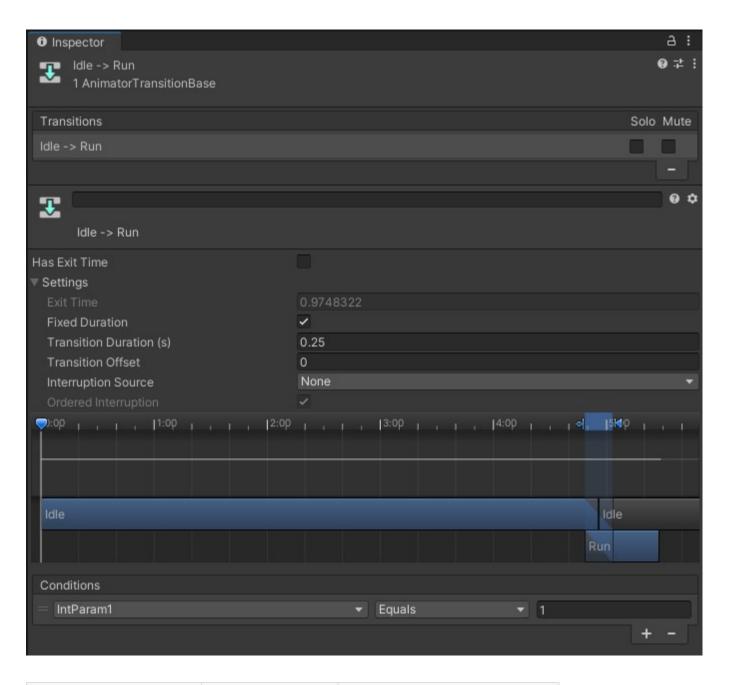

Feature Name	Support Status	Additional Notes
Multiple Layers	✓	
Sub-State Machines	✓	
Weight	✓	
Mask	<u> </u>	
Override Blending	✓	
Additive Blending	<u> </u>	
Sync	×
